

ML Estimate of N-Gram LM

$$p(\mathbf{w}_m | \mathbf{w}_{m-n+1}, \dots, \mathbf{w}_{m-1}) = \frac{c(\mathbf{w}_{m-n+1} \dots \mathbf{w}_{m-1} \mathbf{w}_m, D)}{\sum_{u \in V} c(\mathbf{w}_{m-n+1} \dots \mathbf{w}_{m-1} u, D)}$$

- Count of long word sequences may be zero!
 - Not accurate
 - Cause problems when computing the conditional probability $p(\mathbf{w}_m | \mathbf{w}_{m-n+1}, \dots, \mathbf{w}_{m-1})$
- Solution: smoothing
 - Key idea: backoff to shorter N-grams, eventually to unigrams
 - Treat shorter N-gram models as prior in Bayesian estimation
