Observability

Consider a single-output system $(y \in \mathbb{R})$:

$$\dot{x} = Ax + Bu, \qquad y = Cx \qquad \qquad x \in \mathbb{R}^n$$

The Observability Matrix is defined as

$$\mathcal{O}(A,C) = \begin{bmatrix} C \\ CA \\ \vdots \\ CA^{n-1} \end{bmatrix}$$

We say that the above system is observable if its observability matrix $\mathcal{O}(A, C)$ is *invertible*.

(This definition is only true for the single-output case; the multiple-output case involves the rank of $\mathcal{O}(A, C)$.)
