To Wait or Not To Wait, That is the Question!

While the processor waits, should it...

- continuously **poll** the KBSR
- (load its value to check for a key)?
- check KBSR every so often?

What if there's other work to do?

How often should the processor poll?

What if, instead, we **interrupt** the processor's other work when a key is pressed?

slide 9

Interrupts Avoid the Need for Polling

Interrupts allow **asynchronous** interactions.

When a device needs attention

- (such as when a key is pressed),
- the device raises an interrupt, and
- the processor immediately* executes an interrupt handler.

What's an interrupt handler? A subroutine!

*Generally after finishing the current instruction.

slide 10

Interrupts Require Special Handling of Processor State

The code being executed

- when the interrupt is raised
- does not expect the interrupt to occur.

Therefore, all state must be saved:

- all registers (even R7) are callee-saved, and
- condition codes must also be saved.

ISAs other than LC-3 may have additional state.

slide 11

Restoring State Requires New Instructions (RTI)

When an interrupt handler finishes,

- $^{\circ}\,\textsc{processor}$ state must be restored.
- \circ Otherwise, interrupted code must
- assume that state can change
- between any two instructions!Restoring state completely
- requires special instructions.
- ° LC-3 provides RTI (return from interrupt).
