

Inner Loop Shifts “Things” to Find Place for `current`

```
for (index = sorted - 1; 0 < index;
     index--) {
    // inner loop body performs
    // comparison and may copy
    // one thing to adjacent place
}
```

Loop structure is again identical to the integer version of the sort.

slide 21

21

Comparison Requires `is_smaller`

```
if ((*is_smaller) (current,
                   array + (index - 1) * size)) {
    memcpy (array + index * size,
            array + (index - 1) *
            size, size);
} else {
    break;
}
```

Use `is_smaller` to compare `current` with the thing in `array` element `index - 1`.

slide 22

22

Keep Shifting Things Until `current`'s Place is Found

```
if ((*is_smaller) (current,
                   array + (index - 1) * size)) {
    memcpy (array + index * size,
            array + (index - 1) *
            size, size);
} else {
    break;
}
```

If `current` is smaller, copy `array` element `index - 1` over `array` element `index`.

slide 23

23

When `current` is Not Smaller, the Loop is Done

```
if ((*is_smaller) (current,
                   array + (index - 1) * size)) {
    memcpy (array + index * size,
            array + (index - 1) *
            size, size);
} else {
    break;
}
```

Otherwise, we found the right place!
