

Note that the tangent lines drawn to first graph are all below the graph. Also the slopes of tangent lines are increasing as  $x$  moves from left to right. Whereas in the second graph all the tangent lines are above the graph. Also the slopes of tangent lines are decreasing as  $x$  moves from left to right. So here is the definition;

**Definition** If the graph of  $f$  lies

- (i) above all of its tangents on an interval  $I$ , then it is concave upward on  $I$ .
- (ii) below all of its tangents on an interval  $I$ , then it is concave downward on  $I$ .

**Remarks** • By the discussion just before the definition we know that if  $f$  is concave upward then the slope's of the tangent lines is increasing, this means  $f'$  is increasing. Hence the derivative of  $f'$  –which is  $f''$  – is positive on the interval  $f$  is concave up.

• Similarly, if  $f$  is concave downward then the slope's of the tangent lines is decreasing, this means  $f'$  is decreasing. Hence the derivative of  $f'$  –which is  $f''$  – is negative on the interval  $f$  is concave down.

**Theorem(The Concavity Test)** a) If  $f''(x) > 0$  for all  $x$  in an interval  $I$ , then the graph of  $f$  is **concave up** on  $I$ .

b) If  $f''(x) < 0$  for all  $x$  in an interval  $I$ , then the graph of  $f$  is **concave down** on  $I$ .
